Subjective Questions & Answers – Advanced Regression Assignment

Please note that all these questions-answers are already written in jupyter notebook as some answers also include code snippets, hence screenshots have been taken from the jupyter notebook and pasted here for reference.

Subjective Questions & Answers

Question 1

What is the optimal value of alpha for ridge and lasso regression? What will be the changes in the model if you choose double the value of alpha for both ridge and lasso? What will be the most important predictor variables after the change is implemented?

Answer

```
Optimum alpha for Ridge = 10.0
Optimum alpha for Lasso = 0.001

Training and Test scores for Ridge with alpha = 10.0
R2 score (train): 0.9166751151617185
R2 score (test): 0.8704201226046137
RMSE (train): 0.11304414693007461
RMSE (test): 0.15390088041290248
```

Training and Test scores for Ridge with alpha = 20.0 R2 score (train): 0.9165 R2 score (test): 0.8709 RMSE (train): 0.1132 RMSE (test): 0.1536

Training and Test scores for Lasso with alpha = 0.001 R2 score (train): 0.9157339730212566 R2 score (test): 0.8745163217343286 RMSE (train): 0.1136807627429514 RMSE (test): 0.15144883684391255

Training and Test scores for Lasso with alpha = 0.002 R2 score (train): 0.9146 R2 score (test): 0.8759 RMSE (train): 0.1144

RMSE (test): 0.1506

As we see, there is not significant change in R2 score and RMSE score for Ridge regression when value of alpha is doubled. Similarly, there is not significant change in R2 score and RMSE score for Lasso regression when value of alpha is doubled.

The top 5 features are: 1stFirSF (Positive Relation with target variable) 2ndFirSF (Positive Relation with target variable) OverallQual (Positive Relation with target variable) OverallQual (Positive Relation with target variable) YearBuilt (Negative Relation with target variable)

The top 5 important variables continue to remain the same for both, Lasso and Ridge regression, even though we may see a very very small dip in the coefficient value as they move a bit closer to 0.

For example, For Ridge regression with alpha =10, 1stFirSF values goes from 0.125 to 0.122 for alpha=20.0 Similarly, For Lasso regression with alpha=0.001, 1stFirSF values goes from 0.126 to 0.124, for alpha=0.002

This explains that as the value of alpha increases, the penalty term will be impacted and coefficeints slowly tend to reach close to zero and model starts to become less complex. if value of alpha becomes too high, then model would infact start underfitting and give a low training score.

```
In [1010]:
    # Model Building
    ridge_model = Ridge(alpha=20.0)
    ridge_model.fit(X_train_rfe, y_train)

# Predicting
    y_train_pred = ridge_model.predict(X_train_rfe)
    y_test_pred = ridge_model.predict(X_test_rfe)

print("Model Evaluation : Ridge Regression, alpha=20.0")
    print('R2 score (train) : ',round(r2 score(y_train,y_train_pred), 4))
    print('R2 score (test) : ',round(r2_score(y_test,y_test_pred), 4))
    print('RMSE (train) : ', round(np.sqrt(mean_squared_error(y_train, y_train_pred)), 4))

Model Evaluation : Ridge Regression, alpha=20.0
    R2 score (train) : 0.9165
    R2 score (test) : 0.8709
    RMSE (train) : 0.1132
    RMSE (test) : 0.1536
```

```
In [1011]: lasso_model = Lasso(alpha=0.002)
lasso_model.fit(X_train_rfe, y_train)
y_train_pred = lasso_model.predict(X_train_rfe)
y_test_pred = lasso_model.predict(X_test_rfe)

print("Model Evaluation : Lasso Regression, alpha=0.002")
print('R2 score (train) : ',round(r2_score(y_train,y_train_pred), 4))
print('R2 score (test) : ',round(r2_score(y_test,y_test_pred), 4))
print('RMSE (train) : ', round(np.sqrt(mean_squared_error(y_train, y_train_pred)), 4))
print('RMSE (test) : ', round(np.sqrt(mean_squared_error(y_test, y_test_pred)), 4))

Model Evaluation : Lasso Regression, alpha=0.002
R2 score (train) : 0.9146
R2 score (test) : 0.8759
RMSE (train) : 0.1144
RMSE (test) : 0.1506

In [1012]: model_coefficients['Ridge (alpha = 20.0)'] = ridge_model.coef_
model_coefficients['Lasso (alpha = 0.002)'] = lasso_model.coef_
pd.set_option('display.max_rows', None)
model_coefficients
```

Question 2

You have determined the optimal value of lambda for ridge and lasso regression during the assignment. Now, which one will you choose to apply and why?

Answer

Optimum alpha for Ridge = 10.0 Optimum alpha for Lasso = 0.001

Training and Test scores for Ridge with alpha = 10.0

R2 score (train): 0.9166751151617185 R2 score (test): 0.8704201226046137 RMSE (train): 0.11304414693007461 RMSE (test): 0.15390088041290248

Training and Test scores for Lasso with alpha = 0.001

R2 score (train): 0.9157339730212566 R2 score (test): 0.8745163217343286 RMSE (train): 0.1136807627429514 RMSE (test): 0.15144883684391255

Even though the R2 scores and RMSE scores (the evaluation metrics) are similar for both Ridge and Lasso, if we compare them precisely side by side, Lasso provides better R2 score on Test set and a lower RMSE score on Test set, although the difference is not by huge margin compared to Ridge.

SO in this particular case, we have opted to go with Lasso regression.

Question 3

After building the model, you realised that the five most important predictor variables in the lasso model are not available in the incoming data. You will now have to create another model excluding the five most important predictor variables. Which are the five most important predictor variables now?

Answer

Before dropping the Top 5 variables, the Top 5 variables are 1stFirSF (Positive Relation with target variable) 2ndFirSF (Positive Relation with target variable) OverallQual (Positive Relation with target variable) OverallQual (Positive Relation with target variable) OverallQual (Positive Relation with target variable)

After dropping the Top 5 variables, the Top 5 variables are GarageArea, KitchenQual, Fireplaces, LotArea, BsmtQual. All have a positive relation with target variable as the coefficient values are positive.

	Lasso
GarageArea	0.074841

Question 4

How can you make sure that a model is robust and generalisable? What are the implications of the same for the accuracy of the model and why?

Answer:

The model should be generalized so that the test accuracy is not lesser than the training score. The model should be accurate for datasets other than the ones which were used during training.

Bias-variance tradeoff - If our model is too simple and has very few parameters then it may have high bias and low variance. On the other hand if our model has large number of parameters then it's going to have high variance and low bias. So we need to find the right/good balance without overfitting and underfitting the data.

If a model is too complex, it will have low bias and high variance. But as it has overfitted the training data, model will give high accuracy on training dataset, but is more likely to perform poorly in unseen test dataset.

If a model is too simple, it will have high bias and low variance. As it is too simple, it will fail to identify the underlying patterns in the data, and as are sult it will high a low training score as well as test score.

If we take the point in the bais variance trade off graph, where both intersect each other, that point will give perfect balance between bias-variance. It will ensure that model does not overfit while still having good variance.
